"What do Exporters Know?"

Dickstein and Morales (QJE, 2018)

Motivation / Broad Agenda

- Focus on decision-making under uncertainty:
 - Firm/agent forms expectations of variables needed for decisions (future revenues, exchange rates, productivity, etc.)
 - Econometrician does not observe these expectations
- Goal:
 - Infer the preferences of the decision-maker from observed choices
 - Test the content of agents' information sets
 - Conduct policy counterfactuals
- Problem to tackle:
 - Without direct measurement of firms'/agents' expectations (say by elicitation), need to approximate these expectations to make progress

Motivation: Unobserved expectations are common

For firms

- Developing a new product (Bernard et al., 2010).
 - Expectations about future demand?
- Investing in R&D (Aw et al., 2011).
 - Expectations about success of research activity?

For consumers/agents

- Enrolling in college (Manski, 1993)
 - Expectations about returns to schooling?
- Choosing a prescription drug treatment (Dickstein et al., 2019)
 - Expectations about out-of-pocket costs?

Motivation: Export Participation

- The decision to export involves considerable uncertainty
 - Firms enter a foreign market if the expected value of exporting is positive
 - Firms' entry depends on expectations about the future evolution of their own productivity, exchange rates, trade policy, political stability in foreign countries, etc.
- Export promotion or currency stabilization programs affect exports via firms' expectations

What we do:

- Focus on exporters' entry decisions into foreign markets
- Estimate fixed costs of exporting to each destination
- Use standard partial equilibrium model of export participation
 - CES demand, constant marginal cost, and monopolistic competition
 - Benchmark: two period model
 - Extensions (in paper): (a) fully dynamic model (Das et al., 2007); (b) sample selection model (Heckman, 1979).
- Crucially: Do not require that the researcher has perfect knowledge of the content of firms' information sets

Preview of Results

• **First**, we show that assumptions on the agents' information sets matter. In the Chilean export market:

Estimates of fixed costs of exporting (in thousands of year 2000 US\$):

| Exporters' Information | Argentina | U.S. | Japan |
|--|-----------|-------|-------|
| Perfect Foresight | 868 | 1,645 | 2,621 |
| ${\sf Dist.} + {\sf Lag.} {\sf Sales} + {\sf Lag.} {\sf Exports}$ | 349 | 668 | 1,069 |

Dickstein (NYU)

Preview of results

- Second, we use two types of moment inequalities,
 - (1) odds-based and (2) revealed-preference, that allow for **partial knowledge** of exporters' information sets.
- Estimates of fixed costs of exporting:

| Exporters' Information | Argentina | U.S. | Japan |
|--|-----------|------------|------------|
| At least | (79, 103) | (181, 240) | (309, 414) |
| ${\sf Dist.} + {\sf Lag.} {\sf Sales} + {\sf Lag.} {\sf Exports}$ | | | |

Estimates are 40-60% smaller

Preview of results

- Third, we use our inequalities to learn about exporters' true information sets.
- Test whether a set of variables the researcher observes is a subset of exporters' information:

$$\begin{array}{l} \textit{H}_0: \left\{ \begin{array}{l} \text{exporters at least know dist.} \\ + \text{lag. sales} + \text{lag. exports} \end{array} \right\} \\ \\ \textit{H}_0: \left\{ \begin{array}{l} \text{p-value:} = 0.11/0.98 \\ \end{array} \right. \\ \\ \text{p-value:} = 0.02/ < .001 \end{array} \end{array}$$

- More tests:
 - Do large firms have more information than small firms?
 - Do previous exporters have more information?
 - Do firms know more about popular export destinations?

Preview of results

- Fourth, we quantify the value of information.
- Given our bounds on fixed costs, we compute counterfactual entry decisions under different information sets
- With more information, we find:
 - Firms export to fewer markets (3.5-5.7% fewer destination pairs)
 - Overall export revenue in the sector increases 6.4-9.5%
 - Firm profits increase 18-21%

Model: Overview

- Single-agent, partial equilibrium, two period model.
- First period:
 - firms decide whether to export to each country;
 - if they export, they pay fixed export costs;
 - decision depends on expectations about potential export profits;
 - · expectations are rational;
 - exporters' information set is left unspecified.
- Second period:
 - firms observe realized demand, determine optimal price, obtain export profits.

Model: Demand and Supply

- Firms face isoelastic demand in every country,
- Market structure: monopolistic competition in every destination country.
- Constant marginal production cost: cit.
- If a firm exports a positive amount to j, it must pay two additional costs:
 - ullet iceberg trade costs au_{ijt}
 - fixed costs fijt

Dickstein (NYU)

Model: Information Set

- When deciding whether to export to market j in period t, firm i knows:
 - fixed costs of exporting, f_{ijt};
 - information set, \mathcal{J}_{ijt} , relevant for i to predict export revenues.
- \mathcal{J}_{ijt} includes variables i uses to predict:
 - demand conditions in market j, (Y_{jt}, P_{jt})
 - demand shifters, ζ_{ijt}
 - marginal cost of selling to j, $\tau_{ijt}c_{it}$
- ullet Ex: \mathcal{J}_{ijt} might include last period's market size, demand shifters

Dickstein (NYU)

Model: Profits from Exporting

• If firm *i* enters destination market *j*, obtains revenue:

$$r_{ijt} = \left[\frac{\eta}{\eta - 1} \frac{\tau_{ijt} c_{it}}{\zeta_{ijt} P_{jt}}\right]^{1 - \eta} Y_{jt}$$

which we can rewrite

$$r_{ijt} = \alpha_{ijt}r_{iht}, \quad \text{with} \quad \alpha_{ijt} = \left(\frac{\zeta_{iht}}{\zeta_{ijt}}\frac{\tau_{ijt}}{\tau_{iht}}\frac{P_{ht}}{P_{jt}}\right)^{1-\eta}\frac{Y_{jt}}{Y_{ht}}.$$

• The export profits that i would obtain in j if it were to export to t are

$$\pi_{ijt} = \eta^{-1} r_{ijt} - f_{ijt},$$

< □ > < 圖 > < 필 > < 필 > < 필 > < 필 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연 > < 연

Model: Profits from Exporting

• We model fixed export costs as

$$f_{ijt} = \beta_0 + \beta_1 dist_j + \nu_{ijt},$$

with

$$u_{ijt}|(\mathcal{J}_{ijt}, dist_j) \sim \mathbb{N}(0, \sigma^2).$$

Model: Decision to Export

- Firm i's expectations are rational.
- ullet Firm i will export to j if and only if

$$\mathbb{E}[\pi_{ijt}|\mathcal{J}_{ijt},f_{ijt}]\geq 0.$$

• Therefore,

$$\mathcal{P}(\textit{d}_{\textit{ijt}} = 1 | \mathcal{J}_{\textit{ijt}}, \textit{dist}_{\textit{j}}) = \Phi\big(\sigma^{-1}\big(\eta^{-1}\mathbb{E}[\textit{r}_{\textit{ijt}}|\mathcal{J}_{\textit{ijt}}] - \beta_0 - \beta_1 \textit{dist}_{\textit{j}}\big)\big).$$

- Parameters to estimate $\theta^* \equiv (\beta_0, \beta_1, \sigma)$; fix $\eta = 5$
- But, $\mathbb{E}[r_{ijt}|\mathcal{J}_{ijt}]$?

DATA

Dickstein (NYU)

December 3, 2019

17 / 56

Export Data

- Data sources and variables used in the analysis:
 - Chilean customs database:
 - dummy for positive exports: d_{ijt},
 - firm-destination specific exports: r_{ijt} ,
 - Chilean industrial survey:
 - domestic sales: $r_{iht} = r_{it} \sum_{j} r_{ijt}$
 - CEPII:
 - distance to Chile: dist; (in thousands of kilometers)
- Unbalanced panel of firms for the sample period: 1995-2005.
- Sectors:
 - manufacturing of chemicals and chemical products (√)
 - food products (X)

- 266 unique firms
- Restrict to 22 destinations where at least 5 firms export in every year.

ESTIMATION WITH FULL KNOWLEDGE OF EXPORTERS' INFORMATION SETS

Dickstein (NYU) December 3, 2019 20 / 56

Assuming an Information Set

- ullet The model above does not specify the information set $\mathcal{J}_{ijt}.$
- These information sets are generally not observed in trade datasets.
- Under the assumption that

$$\mathcal{J}^{a}_{ijt}=\mathcal{J}_{ijt},$$

the researcher's assumed export probability conditional on $(\mathcal{J}_{iit}^{a}, \textit{dist}_{j})$ is

$$\mathcal{P}(d_{ijt} = 1 | \mathcal{J}_{ijt}^{a}, dist_{j}) = \Phi(\sigma^{-1}(\eta^{-1}\mathbb{E}[r_{ijt}|\mathcal{J}_{ijt}^{a}] - \beta_{0} - \beta_{1}dist_{j})),$$

and the researcher can estimate $\mathbb{E}[r_{ijt}|\mathcal{J}_{ijt}^a]$ non-parametrically.

Assuming an Information Set: Options

Export probability:

$$\mathcal{P}(\textit{d}_{\textit{ijt}} = 1 | \mathcal{J}_{\textit{ijt}}^{\textit{a}}, \textit{dist}_{\textit{j}}) = \Phi \big(\sigma^{-1} \big(\eta^{-1} \mathbb{E}[\textit{r}_{\textit{ijt}} | \mathcal{J}_{\textit{ijt}}^{\textit{a}}] - \beta_0 - \beta_1 \textit{dist}_{\textit{j}} \big) \big),$$

- (1) Perfect foresight
 - $\mathbb{E}[r_{ijt}|\mathcal{J}_{ijt}^a] = r_{ijt}$
- (2) Two-step approach, "minimal information set"
 - ullet Estimate $\mathbb{E}[r_{ijt}|\mathcal{J}_{ijt}^a]$ nonparametrically in a first stage
 - $\mathcal{J}_{ijt}^{a} \equiv (r_{iht-1}, R_{jt-1}, dist_{j})$

ロト 4回 ト 4 恵 ト 4 恵 ト 「恵」 夕久で

Dickstein (NYU)

Assuming an Information Set: Bias?

ullet If the assumption that $\mathcal{J}^a_{iit}=\mathcal{J}_{ijt}$ is incorrect, the right export probability is

$$\begin{split} \mathcal{P}(\textit{d}_{\textit{ijt}} = 1 | \mathcal{J}_{\textit{ijt}}^{\textit{a}}, \textit{dist}_{\textit{j}}) = \\ \int_{\xi} \Phi\big(\sigma^{-1}\big(\eta^{-1}\mathbb{E}[\textit{r}_{\textit{ijt}}|\mathcal{J}_{\textit{ijt}}^{\textit{a}}] - \beta_0 - \beta_1 \textit{dist}_{\textit{j}} - \eta^{-1}\xi\big)\big) f\big(\xi|\mathcal{J}_{\textit{ijt}}^{\textit{a}}, \textit{dist}_{\textit{j}}\big), \end{split}$$

where

$$\xi_{ijt} \equiv \mathbb{E}[r_{ijt}|\mathcal{J}_{ijt}^a] - \mathbb{E}[r_{ijt}|\mathcal{J}_{ijt}].$$

• The bias in the estimates of $(\beta_0, \beta_1, \sigma)$ depends on

$$f(\xi_{ijt}|\mathcal{J}_{ijt}^a, dist_j).$$

◆ロト 4周ト 4 重ト 4 重 ト 9 Q (?)

Example: Bias when $\mathcal{J}_{ijt}\subset\mathcal{J}^a_{ijt}$

- Perfect foresight case: $\mathbb{E}[r_{ijt}|\mathcal{J}_{ijt}^a] = r_{ijt}$.
- Under perfect foresight:
 - True expectational error: $\varepsilon_{ijt} = r_{ijt} \mathbb{E}[r_{ijt} | \mathcal{J}_{ijt}]$
 - Diff with researcher's proxy: $\xi_{ijt} = \mathbb{E}[r_{ijt}|\mathcal{J}^a_{ijt}] \mathbb{E}[r_{ijt}|\mathcal{J}_{ijt}]$
- Assuming rational expectations implies $cov(\varepsilon_{ijt}, r_{ijt}) > 0$.
- Therefore, wrongly assuming perfect foresight is equivalent to introducing classical measurement error in firms' expectations

$$cov(\xi_{ijt}, \mathbb{E}[r_{ijt}|\mathcal{J}_{ijt}^a]) > 0.$$

• Given normalization by η , upward bias in estimates of $(\beta_0, \beta_1, \sigma)$.

Average Fixed Export Costs - Chemicals

• Under perfect foresight (\$000s (year 2000)):

| Argentina | U.S. | Japan |
|------------|----------------|----------------|
| 868 | 1,645 | 2,621 |
| (767, 969) | (1,454, 1,836) | (2,309, 2,934) |

• Under minimal information set (\$000s (year 2000)):

| Argentina | U.S. | Japan |
|------------|------------|--------------|
| 349 | 668 | 1,069 |
| (323, 374) | (621, 716) | (989, 1,150) |

• Perfect foresight estimates 2.5 times larger

ESTIMATION WITH PARTIAL KNOWLEDGE OF EXPORTERS' INFORMATION SETS

26 / 56

Exporters' Information Sets are Partially Observed

- We assume firms are likely to know at least:
 - lagged own domestic sales: r_{iht-1} ,
 - lagged aggregate exports from Chile to each destination: R_{it-1} ,
 - distance from Chile: dist_i.
- Under the assumption that firms' information sets are only partially observed, the model parameters are only partially identified.
- We define two types of moment inequalities,
 - odds-based
 - revealed-preference

Dickstein (NYU)

27 / 56

Odds-Based Moment Inequalities

• If $Z_{ijt} \subseteq \mathcal{J}_{ijt}$, then

$$\mathcal{M}^{ob}(Z_{ijt};\theta^*) = \mathbb{E}\left[\begin{array}{c} m_l^{ob}(d_{ijt},r_{ijt},dist_j;\theta^*) \\ m_u^{ob}(d_{ijt},r_{ijt},dist_j;\theta^*) \end{array} \middle| Z_{ijt} \right] \geq 0,$$

with

$$\begin{split} & \textit{m}^{ob}_{\textit{l}}(\cdot) = \textit{d}_{\textit{ijt}} \frac{1 - \Phi\left(\sigma^{-1}\left(\eta^{-1}\textit{r}_{\textit{ijt}} - \beta_{0} - \beta_{1}\textit{dist}_{\textit{j}}\right)\right)}{\Phi\left(\sigma^{-1}\left(\eta^{-1}\textit{r}_{\textit{ijt}} - \beta_{0} - \beta_{1}\textit{dist}_{\textit{j}}\right)\right)} - (1 - \textit{d}_{\textit{ijt}}), \\ & \textit{m}^{ob}_{\textit{u}}(\cdot) = (1 - \textit{d}_{\textit{ijt}}) \frac{\Phi\left(\sigma^{-1}\left(\eta^{-1}\textit{r}_{\textit{ijt}} - \beta_{0} - \beta_{1}\textit{dist}_{\textit{j}}\right)\right)}{1 - \Phi\left(\sigma^{-1}\left(\eta^{-1}\textit{r}_{\textit{ijt}} - \beta_{0} - \beta_{1}\textit{dist}_{\textit{j}}\right)\right)} - \textit{d}_{\textit{ijt}}. \end{split}$$

ullet We denote $\mathcal{M}^{ob}(\cdot)$ as the conditional **odds-based moment inequalities**.

4□ > 4□ > 4 = > 4 = > = 90

Dickstein (NYU)

Odds-Based Moment Inequalities: Derivation

ullet Log-likelihood conditional on \mathcal{J} , dist

$$\textit{L}(\textit{d}|\mathcal{J}, \textit{dist}; \theta) = \mathbb{E}\Big[\textit{d}\log(1 - \Phi(-\theta X^*)) + (1 - \textit{d})\log(\Phi(-\theta X^*))|\mathcal{J}, \textit{dist}_j].$$

where

$$\theta X^* = \sigma_{\nu}^{-1}(\eta^{-1}\mathbb{E}[r|\mathcal{J}] - \beta_0 - \beta_1 dist),$$

• The score function:

$$\frac{\partial L(d|\mathcal{J},Z;\theta)}{\partial \theta} = \mathbb{E}\left[d\frac{\Phi(-\theta X^*)}{1-\Phi(-\theta X^*)} - (1-d)\middle|\mathcal{J}\right] = 0.$$

ullet BUT, we do not observe $\mathbb{E}[r|\mathcal{J}]$, only $r=\mathbb{E}[r|\mathcal{J}]+arepsilon$

Dickstein (NYU)

Odds-Based Moment Inequalities: Derivation

- We rely on two assumptions:
 - \bullet Rational expectations $\mathbb{E}[\varepsilon|\mathcal{J}]=0$
 - F(.) chosen such that $\frac{F(y)}{1-F(y)}$ is convex for any value of y
- Then, by Jensen's inequality:

$$\mathbb{E}\left[\frac{\Phi(-\theta X)}{1-\Phi(-\theta X)}\bigg|\mathcal{J}\right] \geq \mathbb{E}\left[\frac{\Phi(-\theta X^*)}{1-\Phi(-\theta X^*)}\bigg|\mathcal{J}\right].$$

• Therefore, we can conclude that

$$\mathbb{E}\bigg[d\frac{\Phi(-\theta X)}{1-\Phi(-\theta X)}-(1-d)\bigg|\mathcal{J}\bigg]\geq 0.$$

Proof sketch in detail

Revealed-Preference Moment Inequalities

• If $Z_{ijt} \subseteq \mathcal{J}_{ijt}$, then

$$\mathcal{M}^r(Z_{ijt}; \theta^*) = \mathbb{E}\left[egin{array}{c} m_l^r(d_{ijt}, r_{ijt}, \mathit{dist}_j; \theta^*) \ m_u^r(d_{ijt}, r_{ijt}, \mathit{dist}_j; \theta^*) \end{array} \middle| Z_{ijt}
ight] \geq 0,$$

with

$$\begin{split} m_{l}'(\cdot) &= -(1-d_{ijt})\big(\eta^{-1}r_{ijt} - \beta_{0} - \beta_{1}dist_{j}\big) + d_{ijt}\sigma\frac{\phi\big(\sigma^{-1}(\eta^{-1}r_{ijt} - \beta_{0} - \beta_{1}dist_{j})\big)}{\Phi\big(\sigma^{-1}(\eta^{-1}r_{ijt} - \beta_{0} - \beta_{1}dist_{j})\big)} \\ m_{u}'(\cdot) &= d_{ijt}\big(\eta^{-1}r_{ijt} - \beta_{0} - \beta_{1}dist_{j}\big) + (1-d_{ijt})\sigma\frac{\phi\big(\sigma^{-1}(\eta^{-1}r_{ijt} - \beta_{0} - \beta_{1}dist_{j})\big)}{1 - \Phi\big(\sigma^{-1}(\eta^{-1}r_{ijt} - \beta_{0} - \beta_{1}dist_{j})\big)}. \end{split}$$

• We denote $\mathcal{M}^r(\cdot)$ as the conditional **revealed-preference moment** inequalities.

Proof sketch in detail

Dickstein (NYU)

Inference Procedure

- Use odds-based and revealed-preference inequalities
- Compute the confidence set for θ^* via Andrews and Soares (2010):
 - Test statistic: use 'modified method of moments'
 - Critical value: use 'generalized moment selection' and the Bayesian Information Criterion constant
- We base inference on a finite set of unconditional moment inequalities.

Average Fixed Export Costs

Table: Average Fixed Export Costs (95% confidence set)

| Sector | Argentina | U.S. | Japan | |
|-----------|-----------|------------|------------|--|
| Chemicals | (80, 103) | (181, 244) | (309, 421) | |

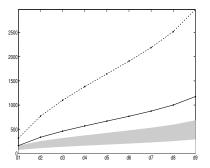

Table: Fixed Export Costs Relative to Perfect Foresight Estimates

| | Chemicals | | | |
|---------------|---------------|----------------|----------------|--|
| Estimator | Argentina | Japan | United States | |
| Minimal Info. | 40.2% | 40.8% | 62.0% | |
| Moment Ineq. | [9.1%, 11.9%] | [11.8%, 15.8%] | [11.1%, 14.6%] | |

• This table reports the ratio of (a) the minimal information ML point estimates and (b) extremes of the moment inequality confidence set, compared to the perfect foresight ML point estimate. All numbers reported in this table are independent of the value of η .

Distribution of Fixed Export Costs

Figure: Fixed costs (\$000s) to export to the United States, Chemicals

• Perfect foresight (dashed), two step (solid), inequalities (gray) nearly coincide at the lowest quantiles.

TESTING FIRMS' INFORMATION SETS

Dickstein (NYU)

35 / 56

Testing Firms' Information Sets

- Given a set of moment inequalities, we test the null hypothesis that there
 exists at least one value of the parameters consistent with all inequalities.
- Intuitively, our test is a test of validity of moments.
- Conditional on the model, this is a test of the null hypothesis that

$$Z_{ijt} \subseteq \mathcal{J}_{ijt}$$
.

ullet We perform multiple model tests in which we vary the vector Z_{ijt} .

Table: Testing Content of Information Sets, Chemicals Sector

| Set of Firms | Set of Export | Individual | Adjusted | Reject | | |
|--|------------------|---------------|------------|--------|--|--|
| | Destinations | p-value | p-value | at 5% | | |
| | Panel A: Minima | l Information | | | | |
| All | All | 0.111 | 0.111 | No | | |
| | Panel B: Perfec | t Foresight | | | | |
| All | All | 0.023 | 0.023 | Yes | | |
| Panel C: I | Minimal Informat | ion & Count | ry Shifter | | | |
| Large | Popular | 0.144 | 0.418 | No | | |
| Small | Popular | < 0.001 | < 0.001 | Yes | | |
| Large Exporter | All | 0.104 | 0.418 | No | | |
| Large Non-exporter | All | 0.140 | 0.418 | No | | |
| Small Exporter | All | < 0.001 | < 0.001 | Yes | | |
| Small Non-exporter | All | < 0.001 | < 0.001 | Yes | | |
| Panel D: Minimal Information & Number of Exporters | | | | | | |
| Large Exporter | All | 0.018 | 0.080 | No | | |
| Large Non-exporter | All | 0.016 | 0.080 | No | | |
| Small Exporter | All | < 0.001 | < 0.001 | Yes | | |
| Small Non-exporter | All | < 0.001 | < 0.001 | Yes | | |
| | | | | | | |

Note: minimal info = $(dist_j, r_{iht-1}, R_{jt-1})$. P-values from Bugni et al. (2015).

What do Exporters Know?

- We reject that firms have perfect foresight.
- We fail to reject that potential exporters know at least the baseline information set
- Large vs. small: Large firms possess relevant information about potential export revenues that small firms do not possess.
- Gathering information from others? —no evidence using popularity of markets
- Gathering information from experience? no evidence using past export experience

Counterfactuals: Information Intervention

Provide minimally informed firms with more information

- Share every destination's lagged aggregate revenue shock $\alpha_{j,t-1}$ (country shifter)
- Share all information needed to perfectly predict observed component of export revenues ("perfect foresight")

How does this help?

- In model, firms obtain all relevant information upon entering a market
- Intervention changes the set of firms that select into each market

39 / 56

Dickstein (NYU) December 3, 2019

Table: Effect of Improving Information: Chemical Sector

| | | Percentage Change in: | | | | |
|---------|---|--------------------------------|-----------------|--------------|--|--|
| | | Number of Mean Export Aggregat | | | | |
| Firms | Markets | Exporters | Profits | Exports | | |

"Hospital Choices, Hospital Prices, and Financial Incentives to Physicians" Ho and Pakes (AER, 2014)

41 / 56

Dickstein (NYU) December 3, 2019

Ho and Pakes (2014)

Research Goals:

- Health: Investigate the effect of physician incentives on costs/quality of hospital care.
 - Specifically, for privately insured patients giving birth, do capitated physicians refer patients to lower-cost hospitals? Lower-quality hospitals?
- Methodology: Illustrate the value of moment inequality methods to allow (a) many fixed effects and (b) measurement/expectational error in covariates

Approach:

- Estimate a hospital referral model
- Compare physicians with "shared risk arrangements" vs. those without

42 / 56

Dickstein (NYU) December 3, 2019

Hospital Referral Model

- Choices in model depend on: (a) hospital prices, (b) distance from patient to hospital, and (c) severity-specific measure of "hospital quality"
- Why is this difficult to estimate?
 - Authors do not observe physician choices directly. Use share of an insurer's patients under capitation
 - Poor measure of hospital prices (list prices + average discount)
 - Poor measure of price expectations (true expectations may differ from both the econometrician's measure of price and true price)
 - Price is endogenous; likely correlated with unobserved hospital quality.
 Difficult to include severity x hospital FE (incidental parameters)
- How to solve? Define moment inequalities

Step 1: Illustrate the limitations of a traditional logit

| Table 5—logit A | NALYSIS RESULTS |
|-----------------|-----------------|
|-----------------|-----------------|

| | All birth patients | Lea | st sick patie | nts | Si | ckest patient | s |
|---------------------------------|---------------------|---------------------|---------------------|---------------------|---------------------|---------------------|---------------------|
| Price | 0.010** (0.002) | -0.017* (0.009) | | 0.069** (0.014) | 0.012** (0.002) | | 0.028** (0.006) |
| Price interactions: | | | | | | | |
| Percent capitated | | | | -0.127** (0.016) | | | -0.025** (0.008) |
| Pacificare | | | -0.077** (0.012) | | | -0.006 (0.006) | |
| Aetna | | | -0.011 (0.016) | | | 0.021** (0.008) | |
| Health Net | | | -0.038** (0.011) | | | 0.007 (0.005) | |
| Cigna | | | -0.021 (0.014) | | | 0.004 (0.007) | |
| Blue Shield | | | 0.018 (0.011) | | | 0.024** (0.004) | |
| Blue Cross | | | 0.008 (0.011) | | | 0.014** (0.003) | |
| Distance | -0.215** (0.001) | -0.215** (0.002) | -0.215** (0.002) | -0.215** (0.002) | -0.217** (0.002) | -0.216** (0.002) | -0.216** (0.002) |
| Distance squared | 0.001** (0.000) | 0.001** (0.000) | 0.001** (0.000) | 0.001** (0.000) | 0.001** (0.000) | 0.001** (0.000) | 0.001** (0.000) |
| $z_h x_i$ controls (15 coeffts) | Y | Y | Y | Y | Y | Y | Y |
| Hospital FEs (194 coeffts) | Y | Y | Y | Y | Y | Y | Y |
| Observations | 88,157 | 43,742 | 43,742 | 43,742 | 44,059 | 44,059 | 44,059 |

- Errors in price variable, limited fixed effects to capture severity x hospital quality leads to upward bias in price coefficient
- Narrowing the sample to homogenous diagnosis groups leads to negative price_coefficient, and a sample to homogenous diagnosis groups leads to negative price_coefficient.

44 / 56

Step 2: Introduce Moment Inequalities

 Choice function is additively separable in the insurer's price, insurer- and severity-specific hospital quality, and distance to the hospital

$$W_{i,\pi,h} = \theta_{p,\pi} p(c_i, h, \pi) + g_{\pi}(q_h(s), s_i) + f_{\pi}(d(l_i, l_h))$$

- Identify pairs of patients with the same severity and the same insurer, but who choose different hospitals.
- Sum the two patients' revealed preference inequalities, thus differencing out the severity-specific hospital quality terms

$$\Delta W(i, h, h') + \Delta W(i', h', h) = \theta_{p,\pi} [\Delta p(c_i, h, h') + \Delta p(c_i', h', h)]) + [\Delta f_{\pi}(l_i, l_h, l_{h'}) + \Delta f_{\pi}(l_{i'}, l_{h'}, l_h)]$$

 Average inequalities over patients and hospitals to eliminate the effects of the errors in the price measurement.

Dickstein (NYU) December 3, 2019

<□ > →□ → → □ > → □ →

Step 2: Introduce Moment Inequalities

$$\Delta W(i, h, h') + \Delta W(i', h', h) = \\ \theta_{p,\pi}[\Delta p(c_i, h, h') + \Delta p(c_i', h', h)]) + [\Delta f_{\pi}(l_i, l_h, l_{h'}) + \Delta f_{\pi}(l_{i'}, l_{h'}, l_h)]$$

Comments:

- Differences out quality/severity terms; can define many interactions
- To find price coefficient, need differences in prices across consumers at the same hospitals (for the same insurer). How?
 - different service use for same severity
 - different services leading to different prices can affect hospital choice only through price
- No (i, h) specific structural error (known to the agent)

Comparison of Logit and Inequality Results

TABLE 10—MAGNITUDES OF LOGIT AND INEQUALITY RESULTS

| | Percent capitated | Logits (less-sick patients) average η_i | Inequalities (all patients) average η_i |
|-------------|-------------------|--|--|
| Pacificare | 0.97 | 0.33 | 11.08 |
| Aetna | 0.91 | 0.10 | 11.47 |
| Health Net | 0.80 | 0.15 | 6.52 |
| Cigna | 0.75 | 0.10 | 2.49 |
| Blue Shield | 0.57 | -0.08 | 0.51 |
| Blue Cross | 0.38 | -0.03 | 3.24 |

Notes: Estimated cross-patient average value of $\eta_i = \frac{\partial d_i}{\partial p_i} \frac{p_i}{d_i}$ for each insurer implied by logit and inequality analyses. logit model uses less-sick population as defined in notes to Table 5. Inequality model uses price defined using discount δ_h (column 1 of Table 7).

- Measures, on average, how much further the consumer would have to drive (in percentage terms) to offset a one percent price increase.
- Compares the elasticity from the logit estimates for the least sick patients vs. elasticities computed from inequalities

47 / 56

Bias: Yatchew and Griliches (1985)

In the specific case in which perfect foresight is assumed

$$\mathbb{E}[r_{ijt}|\mathcal{J}_{ijt}^a]=r_{ijt},$$

agent's true expectations are normally distributed

$$\mathbb{E}[r_{ijt}|\mathcal{J}_{ijt}] \sim \mathbb{N}(0, \sigma_e^2),$$

and the expectational error is normal conditional on agents' information sets

$$\varepsilon_{ijt}|(\mathcal{J}_{ijt}, \nu_{ijt}) \sim \mathbb{N}(0, \sigma_{\varepsilon}^2),$$

there is an upward bias in the estimates of β_0 and β_1 .

• Bias increases in $\sigma_{\varepsilon}^2/\sigma_{e}^2$.

Bias Due to Misspecified Information Sets

Table: Bias under Perfect Foresight

| Model | Distribution of $\mathbb{E}[r_{ijt} \mathcal{J}_{ijt}]$ | Distribution of ξ_{ijt} | Upward Bias in eta_0 |
|-------|---|--|------------------------|
| 1 | $\mathbb{N}(0,1)$ | $\mathbb{N}(0, 0.25)$ | 31% |
| 2 | $\mathbb{N}(0,1)$ | $\mathbb{N}(0,0.5)$ | 49% |
| 3 | $\mathbb{N}(0,1)$ | $\mathbb{N}(0,1)$ | 124% |
| 4 | t_2 | t_2 | 241% |
| 5 | t_5 | t_5 | 131% |
| 6 | t_{20} | t_{20} | 125% |
| 7 | <i>t</i> ₅₀ | <i>t</i> ₅₀ | 124% |
| 8 | $log	ext{-}normal(0,1)$ | $log	ext{-}normal(0,1)$ | 274% |
| 9 | $-\mathit{log}	ext{-}\mathit{normal}(0,1)$ | $-\mathit{log}	ext{-}\mathit{normal}(0,1)$ | 197% |

- $\mathbb{E}[r_{ijt}|\mathcal{J}_{ijt}] = \text{firms' true expectations (unobserved to the researcher)}$
- $\xi_{ijt} = \text{firms' expectational error (unobserved to the researcher)}$

Bias when $\mathcal{J}^{\mathsf{a}}_{\mathit{ijt}} \subset \mathcal{J}_{\mathit{ijt}}$

- ullet The assumed information set \mathcal{J}^a_{iit} is too small.
- In this case, the difference between the true agents' expectation and the researchers' proxy for it is mean independent of this researchers' proxy:

$$cov(\xi_{ijt}, \mathbb{E}[r_{ijt}|\mathcal{J}_{ijt}^a]) = 0.$$

- The estimates of the variance of fixed export costs are always upward biased.
- Only in the specific case in which the distribution of ν_{ijt} and $\nu_{ijt} + \eta^{-1}\xi_{ijt}$ differ only in their variance, the ML estimates of β_0 and β_1 will be consistent.
- Bias always smaller than when we assume an information set that is too large.

Test of Instrument Relevance

Table: Instrument Relevance for $r_{ijt} = \hat{\alpha}_{jt} r_{iht}$

| | Chemicals | | Food | |
|-------------------|------------------------------|------------------------------|------------------------------|------------------------------|
| Covariates | (1) | (2) | (3) | (4) |
